

Classifying movie reviews: a binary classification problem

The IMDB dataset

- A set of 50,000 highly polarized reviews (positive and negative) from the Internet Movie Database
- 25,000 reviews for training and 25,000 reviews for testing
- Each set consists of 50% negative and 50% positive reviews
- Why use separate training and test sets?
- Loading the IMDB dataset

In [1]:

```
import re, random
import torch
from collections import Counter
from datasets import load_dataset
```

In [2]:

```
ds = load_dataset("imdb")

id2label = {0: "neg", 1: "pos"}
train_list = [(id2label[int(r["label"])], r["text"]) for r in ds["train"]]
test_list = [(id2label[int(r["label"])], r["text"]) for r in ds["test"]]
```

```
/usr/local/lib/python3.12/dist-packages/huggingface_hub/utils/_auth.py:94: UserWarning:
The secret `HF_TOKEN` does not exist in your Colab secrets.
To authenticate with the Hugging Face Hub, create a token in your settings tab (https://huggingface.co/settings/tokens), set it as secret in your Google Colab and restart your session.
You will be able to reuse this secret in all of your notebooks.
Please note that authentication is recommended but still optional to access public models or datasets.

Out[5]: ('neg',
 'Although I have to admit I laughed more watching this movie than the last few comedies I saw.<br /><br />The budget must have consisted of pocket change from the actors. The production values are so low that they actually made it kind of fun to watch. Reminds me of the Robot Monster made up of a guy in a gorilla suit with a cardboard diving helmet on.<br /><br />In one scene a hapless victim gets their arm and leg cut off. Geez, hard to believe but the Black Knight scene from Holy Grail was more realistic. I kept wondering why the victim didn\'t start shouting "None Shall Pass" and "It\'s only a flesh wound, I\'ve had worse". It was one of the funniest scenes I\'ve seen in the past year.<br /><br />The "gladiator/demon" was a stitch too. Between the horribly cheap costume and the geeky look of the guy in it the end result was hysterical.<br /><br />Truly a movie that is bad enough to be watchable. Kind of like seeing a slow motion auto accident on film.<br /><br />')
```

- `train_list` and `test_list` are lists of reviews
 - Each review is a string.
- Originally, the label is 0 or 1, where 0 stands for *negative* and 1 stands for *positive*.

- Let's build vocab from training set.
- We need the vocab to convert the string (i.e., review) into a list of indices.

```
In [6]: # Simple tokenizer (English)
def simple_tokenize(s: str):
    # alphanumeric word tokens, lowercased
    return re.findall(r"\b\w+\b", s.lower())

# Build vocab from training set
#   Keep top-N frequent tokens
MAX_VOCAB = 10000
specials = ["<unk>", "<pad>"]

- Build data pipelines: strings → numbers (specifically, indices)

```
In [10]: label_to_int = {"neg": 0, "pos": 1}

def text_pipeline(x: str):
    ids = [stoi.get(tok, UNK_IDX) for tok in simple_tokenize(x)]
    return torch.tensor(ids, dtype=torch.long)

def label_pipeline(y: str):
    return torch.tensor(label_to_int[y], dtype=torch.float32)
```

```
In [14]: print(train_list[0][1])
print(text_pipeline(train_list[0][1]))
```

Eric Clapton, Jack Bruce and Ginger Baker re-unite to play all their songs from 35 years ago when they formed a trio called "Cream." Those were the psychedelic days of England and America and these guys looked it: all skinny, very long hair, wild clothes and loud music. They played a combination of rock and blues and it was, for the most part, good stuff.

Well, these guys are now 60-something years old and they can still sing and play at a high level as this wonderful DVD concert disc shows us. I was always extremely familiar with Clapton, of course, who has never been out of the limelight, but I didn't know what to expect from Bruce and Baker, neither of whom I hadn't seen in decades. They surprised me. When he was young, Baker was so gaunt he looked like a speed freak near death. Now he looks healthy, in shape and his drum playing was solid. Bruce looked a bit haggard but his voice is great, as good as ever and a pleasure to hear on these old songs. This is just excellent material and performing from guys who know what they're doing.

Some people criticized this show for being low-key. I don't agree with that. I have no complaints. The concert sounded very good. The second song, "Spoonful," was outstanding, the highlight of the concert for me.

Highly recommended.

Batching with collate function

- We define a `collate_batch` that:
 1. tokenizes and numericalizes
 2. pads sequences with the `<pad>` index, and
 3. stacks labels as float tensors (for `BCEWithLogitsLoss`)
- We then build PyTorch `DataLoader`s for the train/valid/test sets.

Building the network

- Note that the input data consists of lists of indices (i.e., tokens), and the labels are scalars.
- First, we map tokens to vectors with an `Embedding` layer.
 - This is a fundamental building block
- Note that the input data consists of lists of indices (i.e., tokens), and the labels are scalars.
- First, we map tokens to vectors with an `Embedding` layer.
 - This is a fundamental building block for natural language models, since raw token IDs carry no semantic meaning.
 - Each token index is mapped to a dense vector of fixed dimensionality (e.g., 128).
 - These vectors are trainable parameters — during training, the embedding matrix is updated so that semantically similar words tend to have similar vectors.
 - In our pipeline, the embedding layer produces a `(batch_size, sequence_length, embed_dim)` tensor (in this example, it will later be pooled into a fixed-size sentence representation).
- Consider a simple stack of fully connected (`Linear`) layers with `relu` activations.
 - `nn.Linear(in_dim, h)`
 - The arguments `in_dim` and `h` represent the number of input nodes and hidden nodes, respectively.
 - *The number of hidden nodes* is a dimension in the representation space of the layer.
 - Recall that `output = dot(W, input) + b`.
 - Then, what is the shape of the weight matrix `W`?

- The dimensionality of the representation space = How much freedom you are allowing the network to have when learning internal representations
- There are two key architecture decisions about a stack of `Linear` layers:
 - How many layers to use
 - How many hidden units to choose for each layer
- In this example, we will use:
 - Two hidden layers with 32 hidden units each
 - A third layer that will output the scalar prediction regarding the sentiment of the input review
- The intermediate layers will use `relu` as their activation function, and the final layer will output a single real value (it can be converted into a probability by applying the sigmoid function).
 - A `relu` (rectified linear unit) is a function meant to zero out negative values, $f(x) = x^+ = \max(0, x)$
 - A sigmoid squashes arbitrary values into the $[0, 1]$ interval, outputting something that can be interpreted as a probability, $f(x) = 1/(1 + \exp(-x))$

No description has been provided for this image

- A sigmoid squashes arbitrary values into the $[0, 1]$ interval, outputting something that can be interpreted as a probability, $f(x) = 1/(1 + \exp(-x))$

```

- Why are the activation functions necessary?
- Finally, we need to choose a loss function and an optimizer.
 - We are dealing with a binary classification problem and the output of our network is a probability. --> `binary_crossentropy` loss
 - $\text{binary_crossentropy}(y_{\text{pred}}, y) = -(y \log(y_{\text{pred}}) + (1-y) \log(1-y_{\text{pred}}))$
 - Note that it is not the only viable choice. For example, `mean_squared_error`.
 - *cross entropy* measures the distance between probability distributions or, in this case, between the ground-truth distribution and the predictions.

```
In [25]: criterion = nn.BCEWithLogitsLoss()
optimizer = optim.Adam(model.parameters(), lr=1e-3)
```

Training and validation loops

- We implement explicit train/eval loops.
- During training we zero gradients, backpropagate, and take an optimizer step.
- Accuracy is computed with `sigmoid(logits) >= 0.5`.

```
In [26]: def binary_accuracy_from_logits(logits, targets):
    probs = torch.sigmoid(logits)
    preds = (probs >= 0.5).float()
    correct = (preds == targets).sum().item()
    return correct / targets.numel()
```

```

- Training the model for 20 epochs in mini-batches of 128 samples.
- At the same time, we will monitor loss and accuracy on the 2,500 samples in a validation set.
- We can plot the training and validation loss (or accuracy).

In [27]:

```
import matplotlib.pyplot as plt

plt.figure()
plt.plot(history["train_loss"], label="train_loss")
plt.plot(history["valid_loss"], label="valid_loss")
plt.xlabel("epoch"); plt.ylabel("loss"); plt.legend(); plt.title("Loss Curves")
plt.show()

plt.figure()
plt.plot(history["train_acc"], label="train_acc")
plt.plot(history["valid_acc"], label="valid_acc")
plt.xlabel("epoch"); plt.ylabel("accuracy"); plt.legend(); plt.title("Accuracy Curv
plt.show()
```

- The training loss decreases with every epoch, and the training accuracy increases with every epoch.
 - This is what we expect when running gradient-descent optimization.
- But that isn't the case for the validation loss and accuracy.
 - They seem to peak at the early epoch.
- Important note: a model that performs better on the training data isn't necessarily a model that will do better on data it has never seen before.
 - *overfitting*
 - The network is quickly overoptimized on the training data, and it learned representations that are specific to the training data.
 - These representations don't generalize to data outside of the training set.
- To prevent overfitting, we could stop training after a specific epoch.
 - We will learn various techniques to mitigate overfitting later.

Prediction on new data with a trained network

- We restore the best validation checkpoint (if any) and evaluate on the held-out test set.

```
In [ ]: print(type(best_state))
<class 'dict'>

In [28]: test_loss, test_acc = run_epoch(test_loader, model, criterion, optimizer=None)
print(f"TEST | loss={test_loss:.4f} acc={test_acc:.4f}")
TEST | loss=0.3215 acc=0.8709
```

Inference examples

- We create a convenience function that predicts the positive sentiment probability for a given sentence by passing it through the same preprocessing pipeline and the trained MLP.

```
In [29]: def predict_sentiment(model, sentence: str):
    model.eval()
    with torch.no_grad():
        x = text_pipeline(sentence).unsqueeze(0).to(DEVICE) # (1, T)
        logit = model(x)
        prob = torch.sigmoid(logit).item()
        return {"prob_pos": prob, "label": "pos" if prob >= 0.5 else "neg"}

examples = [
    "This movie was absolutely fantastic. I loved every minute.",
```

```

    "Terrible plot and wooden acting. I want my time back."
]
for s in examples:
    print(s, "->", predict_sentiment(model, s))

```

This movie was absolutely fantastic. I loved every minute. -> {'prob_pos': 0.9992023 11038971, 'label': 'pos'}

Terrible plot and wooden acting. I want my time back. -> {'prob_pos': 2.596096965135 075e-05, 'label': 'neg'}

Saving the trained model

- We save the learned parameters using `state_dict`. You can later reload them with `load_state_dict` on the same model definition.

```
In [ ]: save_path = "imdb_sentiment_mlp_state_dict.pt"
torch.save(model.state_dict(), save_path)
save_path
```

```
Out[ ]: 'imdb_sentiment_mlp_state_dict.pt'

```

Adding regularization

- Let's consider L2 regularization.
 - Note that L2 regularization is also known as weight decay (Strictly speaking, they are **not exactly the same under all optimizers**).

```
In [ ]: # create a new model
model = SentimentMLP(vocab_size=len(stoi), embed_dim=64, hidden_dims=(32, 32), pad_0=True)

# set weight decay argument
optimizer = optim.Adam(model.parameters(), lr=1e-3, weight_decay=1e-3)

# run again
EPOCHS = 20
history = {"train_loss": [], "train_acc": [], "valid_loss": [], "valid_acc": []}
best_val_acc, best_state = 0.0, None

for epoch in range(1, EPOCHS + 1):
    tr_loss, tr_acc = run_epoch(train_loader, model, criterion, optimizer)
    va_loss, va_acc = run_epoch(valid_loader, model, criterion, optimizer=None)

    history["train_loss"].append(tr_loss)
    history["train_acc"].append(tr_acc)
    history["valid_loss"].append(va_loss)
    history["valid_acc"].append(va_acc)

    print(f"Epoch {epoch:02d} | train_loss={tr_loss:.4f} acc={tr_acc:.4f} | valid_loss={va_loss:.4f} acc={va_acc:.4f}")
    if va_acc > best_val_acc:
        best_val_acc = va_acc
        best_state = {k: v.detach().cpu().clone() for k, v in model.state_dict().items()}

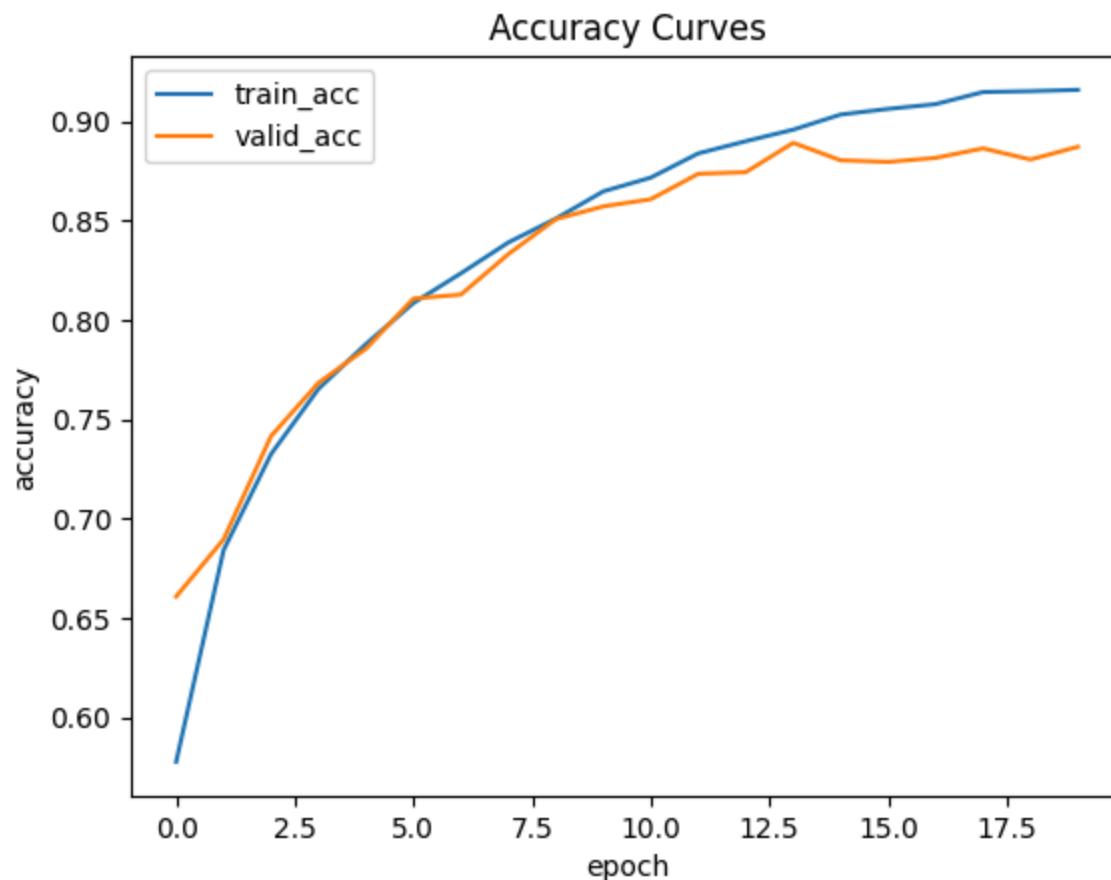

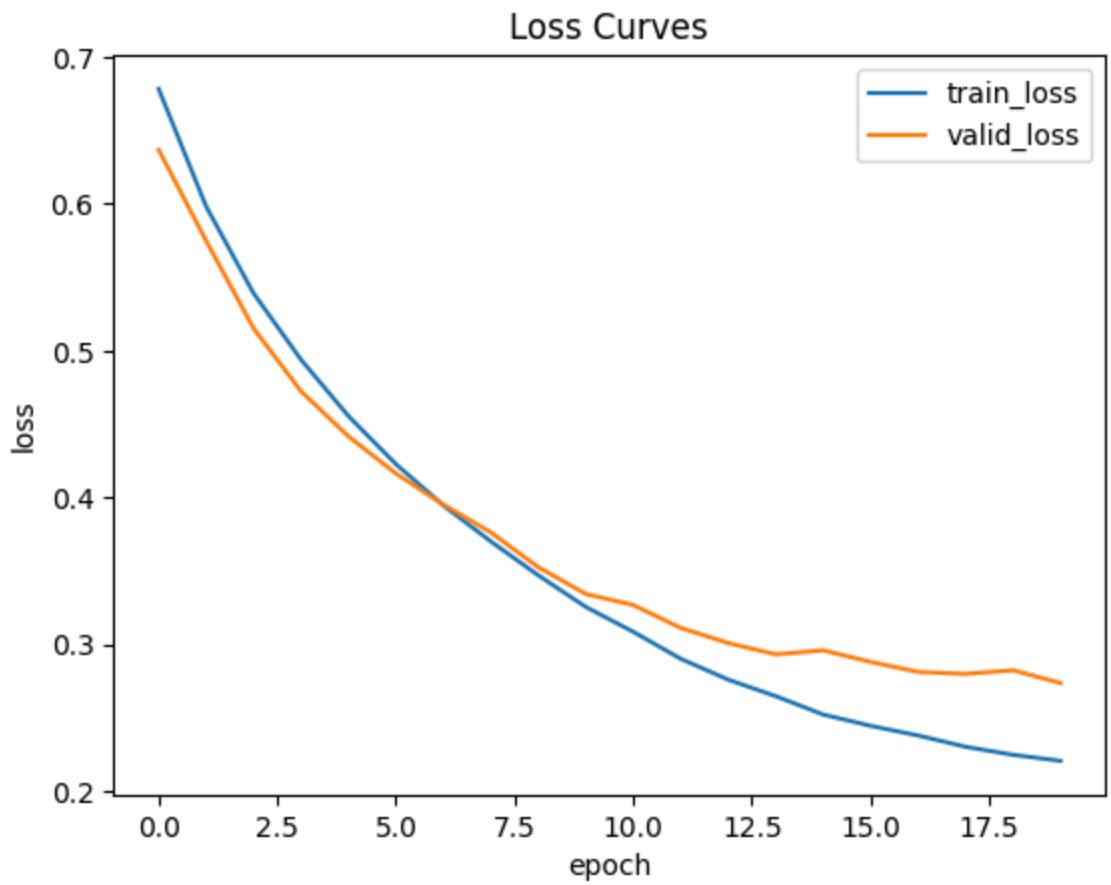

if best_state is not None:
    model.load_state_dict(best_state)
```

```

- Let's consider **dropout**.
 - Dropout* is one of the most effective and most commonly used regularization techniques for neural networks.
 - It consists of randomly dropping out (setting to zero) a number of output features of the layer during training.
 - E.g., [0.2, 0.5, 1.3, 0.8, 1.1] --> (dropout) --> [0, 0.5, 1.3, 0, 1.1]
 - The *dropout rate* is the fraction of the features that are zeroed out (\sim = probability of an element to be zeroed).
 - At test time, no units are dropped out.
 - Instead, the layer's output values are scaled down by a factor equal to *(1-the dropout rate)* to balance for the fact that more units are active than at training time.

 No description has been provided for this image

- Implementation using Numpy

```
# At training time, we zero out 50% of activations.
layer_output *= np.random.randint(0, high=2,
size=layer_output.shape)

# At test time, we scale down the output.
layer_output *= 0.5
```

- Another implementation (in practice)

```
# At training time
layer_output *= np.random.randint(0, high=2,
size=layer_output.shape)
layer_output /= 0.5 # divided by (1-p)
```

- In PyTorch,

```
torch.nn.Dropout(p=0.5)
```

- Adding dropout to the IMDB network

```
In [ ]: class SentimentMLPwithDropout(nn.Module):
    def __init__(self, vocab_size, embed_dim=64, hidden_dims=(32, 32), dropout_p=0.
        super().__init__()
        self.embedding = nn.Embedding(vocab_size, embed_dim, padding_idx=pad_idx if
        layers = []
        in_dim = embed_dim
        for h in hidden_dims:
            layers += [nn.Linear(in_dim, h), nn.ReLU(), nn.Dropout(p=dropout_p)]
            in_dim = h
        layers += [nn.Linear(in_dim, 1)] # output logit
        self.mlp = nn.Sequential(*layers)
```

```

def forward(self, x):

Further experiments

- Try using different number of hidden layers.
- Try using layers with more hidden units or fewer hidden units.
- Try using the `mse` loss function instead of `binary_crossentropy`
- Try using other activation functions (e.g. `tanh`, `sigmoid`) instead of `relu`
- Try other optimizers instead of `Adam`
